Outline

History of information systems

Challenges in using data

Example solutions

New trends & Databricks case study

Pre-Computer Era

Early Business Computers

First used for **operational** applications (automate a business process)

- Bank's account system
- Airline reservations
- Inventory

Each app manages own data
("master file")

1960

master files, reports

1965

lots of master files !!!

- complexity of—
 - maintenance
 - development
- synchronization of data
- hardware

1970

DASD
DBMS

database—“a single source of
data for all processing”

1975

online, high-performance
transaction processing

1980

tx processing

MIS/DSS

PCs, 4GL technology

SQL!

ORACLE®

These databases are great for **operational** applications, but how to use them for **analytics**?

1985

extract program

The Problem

Many systems with data about the same entities

Differing definitions of fields, identifiers, etc

Different points in time

Wrong / low quality data

Challenges in Using Data

These challenges are not unique to operational business apps, but occur in any modern data application / product

Core problem: when the amount of data is more than humans can review, it's hard to tell whether it's correct!

(Things get even harder with statistics and AI)

Solution: disciplines of data architecture & data engineering

Examples

Amazon works with 3 package delivery companies, and Fedex is giving a 10% discount for a year; should it use that?

- Easy business decision

Amazon changes its rec. algorithm to prefer geographically nearby sellers for each item, and profits decrease

- Is the problem incorrect data about seller locations?
- How are we defining geographically near: is it in miles, ship time, etc?
- Did something else cause profits to fall?
- Have sellers or buyers adapted to the change in policy?

Common Challenges in Using Data

Errors at source

Errors loading some of the data, or moving between systems

Inconsistent definition / schema in different locations

Inconsistent downstream calculation

Wrong calculation, metric, etc

Security, governance, performance, cost

How can we address these
challenges?

Idea 1: Data Architectures for Analytics

(Data Warehouses, etc)

PRIMITIVE DATA/OPERATIONAL DATA

- application oriented
- detailed
- accurate, as of the moment of access
- serves the clerical community
- can be updated
- run repetitively
- requirements for processing understood *a priori*
- compatible with the SDLC
- performance sensitive
- accessed a unit at a time
- transaction driven
- control of update a major concern in terms of ownership
- high availability
- managed in its entirety
- nonredundancy
- static structure; variable contents
- small amount of data used in a process
- supports day-to-day operations
- high probability of access

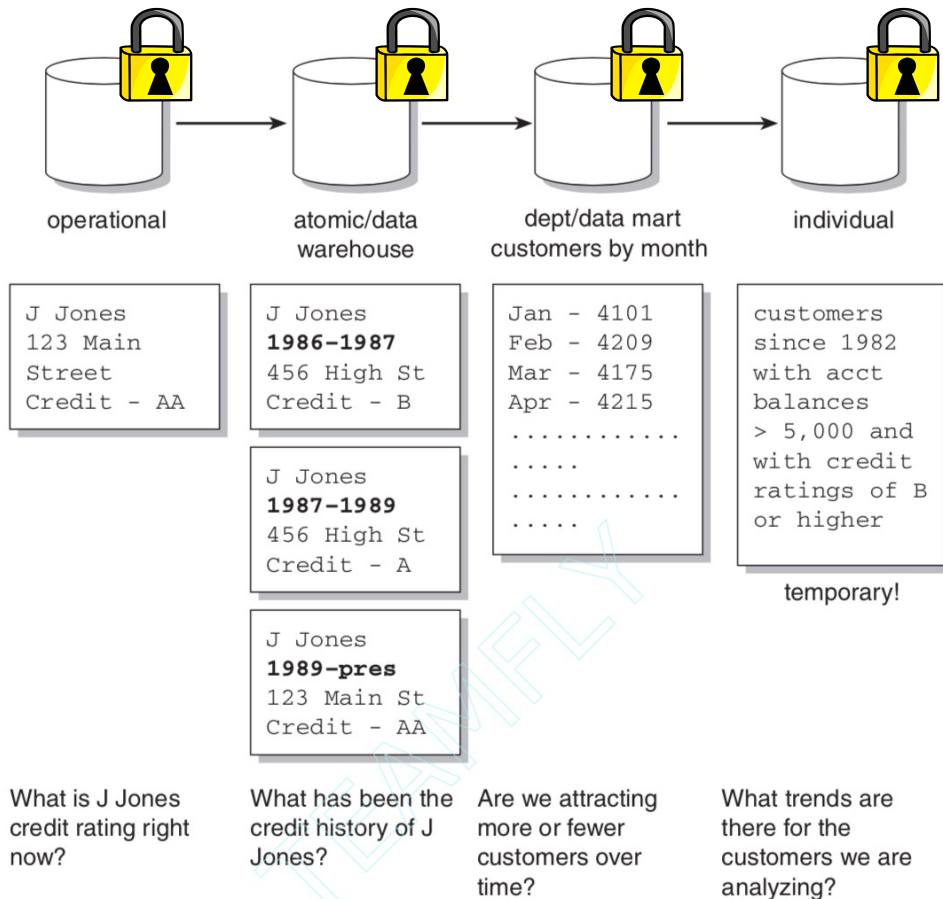

DERIVED DATA/DSS DATA

- subject oriented
- summarized, otherwise refined
- represents values over time, snapshots
- serves the managerial community
- is not updated
- run heuristically
- requirements for processing not understood *a priori*
- completely different life cycle
- performance relaxed
- accessed a set at a time
- analysis driven
- control of update no issue
- relaxed availability
- managed by subsets
- redundancy is a fact of life
- flexible structure
- large amount of data used in a process
- supports managerial needs
- low, modest probability of access

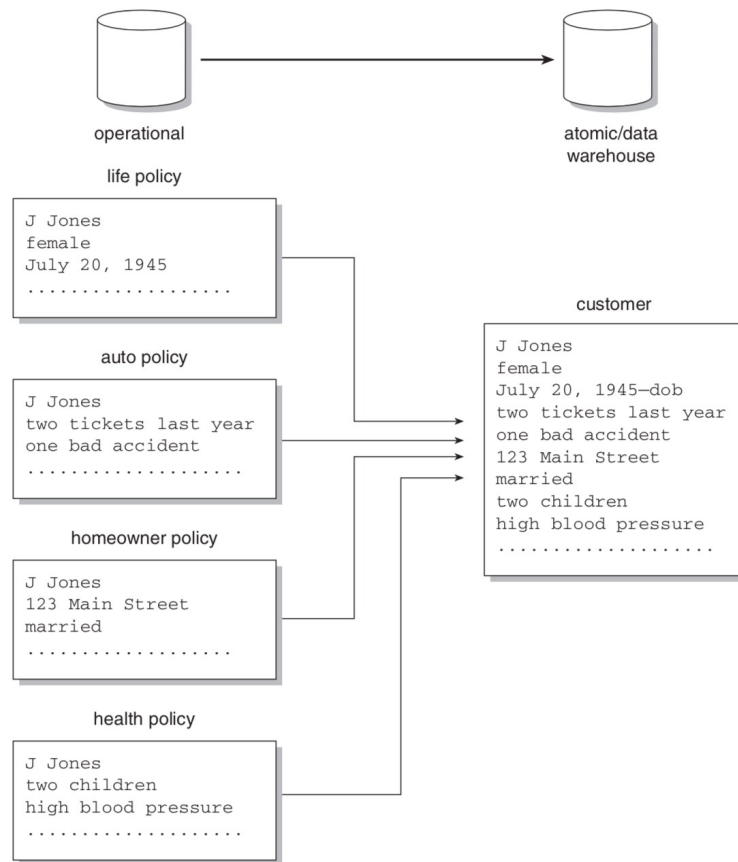

Idea 1: Data Architectures for Analytics

Idea 1: Data Architectures for Analytics

Idea 1: Data Architectures for Analytics

Idea 1: Data Architectures for Analytics

Many implementations today:

- Data warehouse systems (Teradata, Amazon Redshift, BigQuery, ...)
- Data lakes for raw storage (Amazon S3, Apache Hadoop, ...)
- Integrated products for specific use cases (Salesforce, SAP, ...)

Data warehouses

Data lakes

Integrated apps

Other analytics apps

Idea 2: Data Engineering

Apply software engineering principles to data pipelines & outputs

- Testing (at development time)
- Monitoring (at runtime)
- Type checking (schemas, key constraints, etc)
- Separate dev, staging and production environments
- Upgrades with support for rollback, data versioning
- Data pipelines as code

Idea 2: Data Engineering

Historical: database admins and analysts working with structured data in in SQL

Today: expanded to more data types and more code, in programming languages such as Python & Java plus SQL

- The term “data engineer” is fairly new

Welcome to Great Expectations!

Great Expectations is a leading tool for [profiling](#), [validating](#), and

```
batch.expect_column_values_to_be_unique('NPI')

{'success': True,
 'result': {'element_count': 18877,
            'missing_count': 0,
            'missing_percent': 0.0,
            'unexpected_count': 0,
            'unexpected_percent': 0.0,
            'unexpected_percent_nonmissing': 0.0,
            'partial_unexpected_list': []}}
```

Other expectations can be created by examining the data in the batch. For example, suppose you run a pipeline against improper values in the “Provider Other Organization Name Type Code” column. If you don't know exactly what the “improper” values are, you can explore the data by trying some various values. If the data in the batch meets your expectation:

```
batch.expect_column_values_to_be_in_set("Provider Other Organization Name Type Code",
                                       [0, 1, 2, 3])

{'success': False,
 'result': {'element_count': 18877,
            'missing_count': 17819,
            'missing_percent': 94.39529586269005,
```

DATA VALIDATION FOR MACHINE LEARNING

Eric Breck¹ Neoklis Polyzotis¹ Sudip Roy¹ Steven Euijong Whang² Martin Zinkevich¹

ABSTRACT

Machine learning is a powerful tool for gleaming knowledge from massive amounts of data. While a great deal of machine learning research has focused on improving the accuracy and efficiency of training and inference algorithms, there is less attention in the equally important problem of monitoring the quality of data fed to machine learning. The importance of this problem is hard to dispute: errors in the input data can nullify any benefits on speed and accuracy for training and inference. This argument points to a data-centric approach to machine learning that treats training and serving data as an important production asset, on par with the algorithm and

Feature order

Reverse order

Feature search

Features: ☒ int(5) ☒ float(10) ☒ string(2)

	count	missing	mean	std dev	zeros	min	median	max	Chart to show
fare	10,000	0%	11.74	12.13	0.17%	0	0	700.07	Bar
trip_start_hour	10,000	0%	13.63	6.61	4.14%	0	0	23	Bar
dropoff_census_tract	7,148	27.12%	17.08	331k	0%	17.08	0	17.08	Bar
trip_start_timestamp	10,000	0%	1,418	29.2M	0%	1,368	0	1,488	Bar

The previous example assumes that the data is stored in a `TFRecord` file. TFDV also supports CSV input format, with extensibility for other common formats. You can find the available data decoders [here](#). In addition, TFDV provides the `tfdv.generate_statistics_from_dataframe` utility function for users with in-memory data represented as a pandas DataFrame.

Outline

History of information systems

Challenges in using data

Example solutions

New trends & Databricks case study

What's Changing in Data & ML?

Rise of unstructured and “big” data

Originated in web companies but now used well beyond them

- Unstructured data means not tables: for example, images, video, audio, text documents, etc → often the largest data by volume
- New source of “big” tabular data: machine-generated data (e.g. timeseries)

New way to deliver computing technology: public cloud

Rent computer hardware and software as a service (SaaS), pay by usage (e.g. by hour)

Advances in data science & ML

Often enabled by data

Databricks

Founded 2013 by Berkeley researchers that created Apache Spark (open source big data computing engine)

Business model: cloud service over AWS, Azure, etc

- Run & manage computing workloads for customers

>5000 customers, ~2000 employees

- 10+ million VMs processing exabytes of data per day

Usage Growth: VMs/day

Example Use Cases

REGENERON

Correlate 500,000 patient records with DNA to design therapies

Optimize inventory management using simulations and ML

Identify securities fraud via machine learning on 30 PB of data

Databricks Product: “Lakehouse” Platform

Takeaways from Databricks

1. Simplify building production data apps
2. Rise of cloud computing
3. Interesting use cases and challenges

Takeaways from Databricks

1. Simplify building production data apps
2. Rise of cloud computing
3. Interesting use cases and challenges

Simplify Building Production Data Apps

Most data apps have yet to be written, especially for new data sources (e.g. big data) or new techniques (e.g. ML)

Most of the effort in these apps goes to reliably combining and preparing the relevant data (in a way that keeps running later!)

Cleaning Big Data: Most Time-Consuming, Least Enjoyable Data Science Task, Survey Says

Gil Press Contributor

Home > Analytics > Data Science

The 80/20 data science dilemma

Most data scientists spend only 20 percent of their time on actual data analysis and 80 percent of their time finding, cleaning, and reorganizing huge amounts of data, which is an inefficient data strategy

Simplify Building Production Data Apps

Most data apps have yet to be written, especially for new data sources (e.g. big data) or new techniques (e.g. ML)

Most of the effort in these apps goes to reliably combining and preparing the relevant data (in a way that keeps running later!)

→ Figure out ways to let **more people** build **reliable** apps

Example: Data Science Report

Alex the data scientist wants to publish a sales forecast each day based on machine-generated & customer data

Before Databricks: Alex needs to work with a data engineer and DB admin to create data loading jobs in Java and SQL, then get them to deploy and run these jobs

After Databricks: Alex can use Spark API to access both unstructured & structured data in a Python notebook, schedule the notebook as a job, and run it on her own cloud VMs

Big difference in productivity even at eng-heavy companies

Example: Business Intelligence

Before Databricks: Business analysts need to wait for data to be loaded into a data warehouse to do analytics in Tableau (and even then, only a subset of data is in there)

After Databricks: Business analysts can connect Tableau to the entire data lake and query all data in the organization as soon as it arrives

Focus on maximizing **access, reliability & timeliness** of data

Production Gap in Machine Learning

ML Research & Courses

Goal: designing a good model

Data is provided and ready to use
(e.g. benchmark dataset)

No need to deploy, monitor, retrain or
implement governance

Tools for model design & evaluation
(e.g. TensorFlow, SciKit)

ML Products

Goal: reliably solving a business problem

Data is often the biggest challenge
(for models, try many standard ones)

Must continuously deploy + monitor +
retrain, and have governance

Need new tools to enable this process!
(ML platforms such as MLflow)

Takeaways from Databricks

1. Simplify building production data apps
2. Rise of cloud computing
3. Interesting use cases and challenges

Traditional Software

Vendor

Dev Team

6-12 months

Release

6-12 months

Customers

Cloud Software

Dev + Ops Team

1-2 weeks

Why Use Cloud Software?

- 1 **Management built-in:** much more value than the software bits alone (security, availability, etc)
- 2 **Elasticity:** pay-as-you-go, scale on demand
- 3 **Better features** released faster

Differences in Building Cloud Software

- + **Rapid feedback:** release updates any time, monitor usage live
- + **Only need to maintain 2 software versions** (current & next), in fewer configurations than you'd have on-premise
- **Updating without regressions:** very hard, but critical in cloud (includes API, semantics, and performance regressions)
- **Operating a multitenant service:** scaling, security, user isolation

Takeaways from Databricks

1. Simplify building production data apps
2. Rise of cloud computing
3. Interesting use cases and challenges

Interesting Databricks Use Cases

Selling data products to other companies

- **Traditional approach:** charge for monthly access to new data
 - Little room for price discrimination: everyone gets full datasets
- **New approach:** give users a hosted computing platform and charge by query, by seats, or by other metrics (OEM Databricks!)

Example: S&P Marketplace Workbench

Interesting Databricks Use Cases

Surprising sources of big data

- **Network security:** log every network operation to catch intruders, malicious insiders, exfiltration, etc → petabytes of data per day
- **Public datasets:** many biotech and financial companies use these
- **Industrial IoT:** every factory device, airplane engine, etc is instrumented

New Trends and Challenges

Privacy regulations, such as GDPR and CCPA, have required companies to significantly rethink data systems (for the better?)

- Only collect & use data for specific purposes (how to track this?)
- Any user can ask to delete their data (can't store it immutably as before!)
- B2B contracts also increasingly have complex rules

New Trends and Challenges

Production machine learning: ML apps have similar problems to data applications (too much data for human review), but worse:

- Opaque and misaligned metrics
- Overfitting
- Bias

Conclusion

Using data in products and business decisions is hard: need to define, collect, and monitor the data reliably and analyze in depth

Various technologies and principles for this have emerged over time (data engineering, data warehouse architecture, etc)

Lots of room to make this simpler
